Definition 3.1. An integer matrix is in row echelon form if

(1) all nonzero rows (rows with at least one nonzero element) zero rows, if any, belong at the bottom of the matrix), and

(2) the leading coefficient (the first nonzero number from a nonzero row is always strictly to the right of the leading coefficient (the first nonzero number from the nonzero row is always strictly to the right of the leading coefficient (the first nonzero number from the nonzero row is always strictly to the right of the leading coefficient (the first nonzero number from the nonzero row is always strictly to the right of the leading coefficient (the first nonzero number from the nonzero row is always strictly to the right of the leading coefficient (the first nonzero number from the nonzero row is always strictly to the right of the leading coefficient (the first nonzero number from the nonzero row is always strictly to the right of the leading coefficient (the first nonzero number from the nonzero row is always strictly to the right of the leading coefficient (the first nonzero number from the n

You can use specialized software (e.g., wolfram alpha) to compute remainders of division and gcd's. Remainders can be computed by google, e.g., search '620² % 377753'.

- **Exercise 3.1.** [5pts] Show that n = 1105 is a Carmichael number.
- **Exercise 3.2.** [5pts] Use base-2 Miller–Rabin primality test to show that N=341 is composite.

Exercise 3.3. [10pts] For N = 6994241 use Pollard's p-1 algorithm with a=2 to find a non-trivial factor (less than ten iterations will be enough).

Exercise 3.4. [10pts] Let N = 377753. Given the relations

$$620^{2} \equiv_{N} 6647 = 17^{2} \cdot 23,$$

$$621^{2} \equiv_{N} 7888 = 2^{4} \cdot 17 \cdot 29$$

$$645^{2} \equiv_{N} 38272 = 2^{7} \cdot 13 \cdot 23$$

$$655^{2} \equiv_{N} 51272 = 2^{3} \cdot 13 \cdot 17 \cdot 29,$$

find a, b satisfying $a^2 \equiv_N b^2$ and compute gcd(a - b, N).

Exercise 3.5. [10pts] For N = 1111, $f(x) = x^2 + 1$, and $x_1 = 5$ run four iterations (compute four gcds) of the Pollard's rho algorithm and get a non-trivial factor of N.

- (1) all nonzero rows (rows with at least one nonzero element) are above any rows of all zeroes (all
- (2) the **leading coefficient** (the first nonzero number from the left, also called the **pivot**) of a nonzero row is always strictly to the right of the leading coefficient of the row above it.

$$\left[\begin{array}{cccccc} \mathbf{1} & 2 & -1 & 5 & -4 \\ 0 & 0 & \mathbf{2} & 0 & 5 \\ 0 & 0 & 0 & \mathbf{1} & 3 \end{array}\right]$$

A row reduction is a process of reducing a given matrix to a row echelon form.

- Row addition: a row can be replaced by the sum of that row and a (integer!)multiple of

We use elementary row operations to reduce the matrix to a row echelon form. For instance, for

$$\begin{bmatrix}
1 & 0 & -1 \\
2 & 2 & 1 \\
3 & 4 & -2
\end{bmatrix}$$

$$\begin{bmatrix}
1 & 0 & -1 \\
0 & 2 & 3 \\
3 & 4 & -2
\end{bmatrix}$$

 \bullet Add row #1 multiplied by -3 to row #3 to get

$$\left[\begin{array}{ccc}
1 & 0 & -1 \\
0 & 2 & 3 \\
0 & 4 & 1
\end{array}\right]$$

 \bullet Add row #2 multiplied by -2 to row #3 to get

$$\left[\begin{array}{ccc}
1 & 0 & -1 \\
0 & 2 & 3 \\
0 & 0 & 5
\end{array}\right]$$

Exercise 3.6. [10pts] Compute a row echelon form of the matrix

$$\left[\begin{array}{ccc}
2 & 0 & -1 \\
2 & 2 & 1 \\
3 & 4 & -2
\end{array}\right]$$
